## Abstract

We consider the problem of estimating a varying coefficient panel data model with fixed effects using a local linear regression approach. Our proposed estimator can consistently estimate the regression model with an additive intercept term, while the conventional estimation method based on a first difference model fails to do so. The computed estimator is shown to be asymptotically normally distributed. A modified least-squared cross-validatory method is used to select the optimal bandwidth automatically. Moreover, we propose a test statistic for testing the null hypothesis of a random effects against a fixed effects varying coefficient panel data model. Monte Carlo simulations show that proposed estimator and test statistic have satisfactory finite sample performance.

**Key words:** Consistent test; Fixed effects; Panel data; Varying coefficients model.

# 1 Introduction

Panel data traces information on each individual unit across time. This two-dimensional information enables researchers to estimate complex models and extract information and inferences which may not be possible using pure time-series data or cross-section data. With the increased availability of panel data, both theoretical and applied work in panel data analysis has become more popular in the recent years.

Arellano (2003), Baltagi (2005), and Hsiao (2003) provide excellent overview of parametric panel data model analysis. However, it is well known that a misspecified parametric panel data model may give misleading inferences. To avoid imposing the strong restrictions assumed in the parametric panel data models, econometricians and statisticians have worked on theories of nonparametric and semiparametric panel data regression models. For example, Henderson, Carroll, and Li (2008) considered the fixed-effects nonparametric panel data model. Henderson and Ullah (2005), Lin and Carroll (2000, 2001, 2006), Lin, Wang, Welsh and Carroll (2004), Lin and Ying (2001), Ruckstuhl, Welsh and Carroll (1999), Wang (2003), and Wu and Zhang (2002) considered the random-effects nonparametric panel data models. Li and Stengos (1996) considered a partially linear panel data model with some regressors being endogenous via IV approach, and Su and Ullah (2006) investigated a fixed-effects partially linear panel data model with exogenous regressors.

A purely nonparametric model suffers from the ‘course of dimensionality’ problem; while a partially linear semiparametric model may be too restrictive as it only allows for some additive nonlinearities. The varying coefficient model considered in this paper include both pure nonparametric model and partially linear regression model as special cases. Moreover, we assume a fixed-effects panel data model. By fixed effects we mean that the individual effects are correlated with the regressors in an unknown way. Consistent with the well-known results in parametric panel data model estimation, we show that random effects estimators are inconsistent if the true model is one with fixed effects and that fixed effects estimators are consistent under both random and fixed effects panel data model, although the random effects estimator is more efficient than the fixed effects estimator when the random effects model holds true. Therefore, estimation of random effects models are appropriate only when the individual effect is independent of the regressors. As in practice, economists often view the assumptions required for the random effects model as being

unsupported by the data. This paper emphasizes more on estimating a fixed effects panel data varying coefficient model, and we propose to use the local linear method to estimate unknown smooth coefficient functions. We also propose a test statistic for testing a random effects against a fixed effects varying coefficient panel data model. Simulation results show that our proposed estimator and test statistic have satisfactory finite sample performances.

Recently, Cai and Li (2008) studied a dynamic nonparametric panel data model with unknown varying coefficients. As Cai and Li (2008) allow the regressors not appearing in the varying coefficient curves to be endogenous, the GMM-based IV estimation method plus local linear regression approach is used to deliver consistent estimator of the unknown smooth coefficient curves. In this paper, all the regressors are assumed to be exogenous. Therefore, the least-squared method combining with local linear regression approach can be used to produce consistent estimator of the unknown smoothing coefficient curves. In addition, the asymptotic results are given when the time length is finite.

The rest of the paper is organized as follows. In section 2 we set up the model and discuss transformation methods that remove fixed effects. Section 3 proposes a nonparametric fixed effects estimator for a varying coefficient function and derives the asymptotic distribution of the proposed estimator. In section 4 we suggest a statistic for testing the null hypothesis of a random effects against a fixed effects varying coefficient model. Section 5 reports simulation results that examine the finite sample performance of our semiparametric estimator and the test statistic. Finally we concludes the paper in section 6. The proofs of the main results are collected in an Appendix.

## 2 Fixed-Effects Varying Coefficient Panel Data Models

We consider the following fixed-effects varying coefficient panel data regression model

$$Y_{it} = X_{it}^{\top} \theta(Z_{it}) + \mu_i + \nu_{it}, \quad (i = 1, \dots, n; t = 1, \dots, m) \quad (1)$$

where the covariate  $Z_{it} = (Z_{it,1}, \dots, Z_{it,q})^{\top}$  is of dimension  $q$ ,  $X_{it} = (X_{it,1}, \dots, X_{it,p})^{\top}$  is of dimension  $p$ ,  $\theta(\cdot) = \{\theta_1(\cdot), \dots, \theta_p(\cdot)\}^{\top}$  contains  $p$  unknown functions, and all other variables are scalars. The random errors  $\nu_{it}$  are assumed to be i.i.d. with a zero mean, finite variance  $\sigma_v^2$  and independent of  $\mu_i$ ,  $Z_{it}$  and  $X_{it}$  for all  $i$  and  $t$ . The unobserved individual effects  $\mu_i$  are assumed to be i.i.d. with a

zero mean and a finite variance  $\sigma_\mu^2$ . We allow for  $\mu_i$  to be correlated with  $Z_{it}$  and/or  $X_{it}$  with an unknown correlation structure. Hence, model (1) is a fixed-effects model. Alternatively, when  $\mu_i$  is uncorrelated with  $Z_{it}$  and  $X_{it}$  model (1) becomes a random-effects model.

A somewhat simplistic explanation for consideration of fixed effects models and the need for estimation of the function  $\theta(\cdot)$  arises from considerations such as the following. Suppose that  $Y_{it}$  is the (logarithm) income of individual  $i$  at time period  $t$ , and  $X_{it}$  is education of individual  $i$  at time period  $t$ , e.g., number of years of schooling; and  $Z_{it}$  is the age of individual  $i$  at time  $t$ . The fixed effects term  $\mu_i$  in (1) includes the individual's unobservable characteristics such as ability, e.g., IQ level, characteristics which are not observable for the data at hand. In this problem, economists are interested in the marginal effects of education on income, after controlling for the unobservable individual ability factors. Hence, they are interested in the marginal effects in the income change for an additional year of education regardless of whether the person has high or low ability. In this simple example, it is reasonable to believe that ability and education are positively correlated. If one does not control for the unobserved individual effects, then one would over-estimate the true marginal effects of education on income (i.e., with an upwards bias).

When  $X_{it} \equiv 1$  for all  $i$  and  $t$  and  $p = 1$ , model (1) reduces to Henderson, Carroll, and Li's (2008) nonparametric panel data model with fixed effects as a special case. One may also interpret  $X_{it}^\top \theta(Z_{it})$  as an interactive term between  $X_{it}$  and  $Z_{it}$  where we allow  $\theta(Z_{it})$  to have a flexible format since the popularly used parametric setup such as  $Z_{it}$  and/or  $Z_{it}^2$  may be misspecified.

For a given fixed effects model, there are many ways of removing the unknown fixed effects from the model.

The usual first-differencing (FD) estimation method deducts one equation from another to remove the time-invariant fixed effects. For example, deducting equation for time  $t$  from that for time  $t - 1$ , we have for  $t = 2, \dots, m$

$$\tilde{Y}_{it} = Y_{it} - Y_{it-1} = X_{it}^\top \theta(Z_{it}) - X_{it-1}^\top \theta(Z_{it-1}) + \tilde{v}_{it}, \quad \text{with } \tilde{v}_{it} = v_{it} - v_{it-1}; \quad (2)$$

or deducting equation for time  $t$  from that for time 1, we obtain for  $t = 2, \dots, m$

$$\tilde{Y}_{it} = Y_{it} - Y_{i1} = X_{it}^\top \theta(Z_{it}) - X_{i1}^\top \theta(Z_{i1}) + \tilde{v}_{it}, \quad \text{with } \tilde{v}_{it} = v_{it} - v_{i1}. \quad (3)$$

The conventional fixed-effects (FE) estimation method, on the other hand, removes the fixed

effects by deducting each equation from the cross-time average of the system, and it gives for  $t = 2, \dots, m$

$$\begin{aligned}\tilde{Y}_{it} &= Y_{it} - \frac{1}{m} \sum_{s=1}^m Y_{is} = X_{it}^\top \theta(Z_{it}) - \frac{1}{m} \sum_{s=1}^m X_{is}^\top \theta(Z_{is}) + \tilde{v}_{it} \\ &= \sum_{s=1}^m q_{ts} X_{is}^\top \theta(Z_{is}) + \tilde{v}_{it} \quad \text{with } \tilde{v}_{it} = v_{it} - \frac{1}{m} \sum_{s=1}^m v_{is}\end{aligned}\tag{4}$$

where  $q_{ts} = -1/m$  if  $s \neq t$  and  $1 - 1/m$  otherwise, and  $\sum_{s=1}^m q_{ts} = 0$  for all  $t$ .

Many nonparametric local smoothing methods can be used to estimate the unknown function  $\theta(\cdot)$ . However, for each  $i$ , the right-hand of equations (2)-(4) contain linear combination of  $X_{it}^\top \theta(Z_{it})$  for different time  $t$ . If  $X_{it}$  contains an intercept term, say the first component of  $X_{it}$  is identically one, and let  $\theta_1(Z_{it})$  denote the first component of  $\theta(Z_{it})$ , then a first difference of  $X_{it,1} \theta_1(Z_{it}) \equiv \theta_1(Z_{it})$  gives  $\theta_1(Z_{it}) - \theta_1(Z_{i,t-1})$ , which is an additive function with the same function form for the two functions but evaluated at different observation points. Kernel based estimator usually requires some backfitting algorithms to recover the unknown function, which brings not only computational burden but also complicates mathematical proofs. Moreover, if  $\theta_1(Z_{it})$  contains an additive constant term, say  $\theta(Z_{it}) = c + g_1(Z_{it})$ , where  $c$  is a constant, then the first difference will wipe the additive constant  $c$ . As a consequence, one cannot consistently estimate  $\theta_1(\cdot)$  one were to estimate a first difference model.

Therefore, in this paper we consider an alternative way of removing the unknown fixed effects, motivated by a least squares dummy variable (LSDV) model in parametric panel data analysis. We will describe how the proposed method removes fixed effects by deducting a smoothed version of cross-time average from each individual unit. As we will show later, this transformed method will not wipe the additive constant  $c$  in  $\theta_1(Z_{it}) = c + g_1(Z_{it})$ . Therefore, we can consistently estimate  $\theta_1(\cdot)$  as well as other components of  $\theta(\cdot)$ .

We will use  $I_n$  to denote an identity matrix of dimension  $n$ , and  $e_m$  to denote an  $m \times 1$  vector with all elements being ones. Rewriting model (1) in a matrix format yields

$$Y = B\{X, \theta(Z)\} + D_0 \mu_0 + V,\tag{5}$$

where  $Y = (Y_1^\top, \dots, Y_n^\top)^\top$  and  $V = (v_1^\top, \dots, v_n^\top)^\top$  are  $(nm) \times 1$  vectors;  $Y_i^\top = (Y_{i1}, \dots, Y_{in})$  and  $v_i^\top = (v_{i1}, \dots, v_{in})$ .  $B\{X, \theta(Z)\}$  stacks all  $X_{it}^\top \theta(Z_{it})$  into an  $(nm) \times 1$  vector with the  $(i, t)$  subscript

matching that of the  $(nm) \times 1$  vector of  $Y$ ;  $\mu_0 = (\mu_1, \dots, \mu_n)^\top$  is an  $n \times 1$  vector, and  $D_0 = I_n \otimes e_m$  is an  $(nm) \times n$  matrix with main diagonal blocks being  $e_m$ , where  $\otimes$  refers to Kronecker product operation. However, we can not estimate model (5) directly due to the existence of the fixed effects term. Therefore, we need some identification conditions. Su and Ullah (2006) assume  $\sum_{i=1}^n \mu_i = 0$ . We show that assuming an i.i.d sequence of unknown fixed effects,  $\mu_i$ , with zero mean and a finite variance is enough to identify the unknown coefficient curves asymptotically. We therefore impose this weaker version of identification condition in this paper.

To introduce our estimator, we first assume that model (1) holds with the restriction  $\sum_{i=1}^n \mu_i = 0$ . Define  $\mu = (\mu_2, \dots, \mu_n)^\top$ . We then rewrite (5) as

$$Y = B\{X, \theta(Z)\} + D\mu + V, \quad (6)$$

where  $D = [-e_{n-1} \ I_{n-1}]^\top \otimes e_m$  is an  $(nm) \times (n-1)$  matrix. Note that  $D\mu = \mu_0 \otimes e_m$  with  $\mu_0 = (-\sum_{i=2}^n \mu_i, \mu_2, \dots, \mu_n)^\top$  so that the restriction  $\sum_{i=1}^n \mu_i = 0$  is imposed in (6).

Define an  $m \times m$  diagonal matrix  $K_H(Z_i, z) = \text{diag}\{K_H(Z_{i1}, z), \dots, K_H(Z_{im}, z)\}$  for each  $i$ , and a  $(nm) \times (nm)$  diagonal matrix  $W_H(z) = \text{diag}\{K_H(Z_1, z), \dots, K_H(Z_n, z)\}$ , where  $K_H(Z_{it}, z) = K\{H^{-1}(Z_{it} - z)\}$  for all  $i$  and  $t$ , and  $H = \text{diag}(h_1, \dots, h_q)$  is a  $q \times q$  diagonal bandwidth matrix. We then solve the following optimization problem

$$\min_{\theta(Z), \mu} [Y - B\{X, \theta(Z)\} - D\mu]^\top W_H(z) [Y - B\{X, \theta(Z)\} - D\mu], \quad (7)$$

where we use the local weight matrix  $W_H(z)$  to ensure locality of our nonparametric fitting, and place no weight matrix for data variation since the  $\{v_{it}\}$  are i.i.d. across equations. Taking first-order condition with respect to  $\mu$  gives

$$D^\top W_H(z) [Y - B\{X, \theta(Z)\} - D\hat{\mu}(z)] = 0, \quad (8)$$

which yields

$$\hat{\mu}(z) = \{D^\top W_H(z) D\}^{-1} D^\top W_H(z) [Y - B\{X, \theta(Z)\}]. \quad (9)$$

Define  $S_H(z) = M_H(z)^\top W_H(z) M_H(z)$  and  $M_H(z) = I_{n \times m} - D\{D^\top W_H(z) D\}^{-1} D^\top W_H(z)$ , where  $I_{n \times m}$  denotes an identity matrix of dimension  $nm$  by  $nm$ . Replacing  $\mu$  in (7) by  $\hat{\mu}(z)$ , we

obtain the concentrated weighted least squares

$$\min_{\theta(Z)} [Y - B\{X, \theta(Z)\}]^\top S_H(z) [Y - B\{X, \theta(Z)\}], \quad (10)$$

Note that  $M_H(z)D\mu \equiv 0_{(nm) \times 1}$  for all  $z$ . Hence, the fixed effects term  $\mu$  is removed in model (10).

To see how  $M_H(z)$  transform the data, simple calculations give

$$M_H(z) = I_{n \times m} - D\{A^{-1} - A^{-1}e_{n-1}e_{n-1}^\top A^{-1} / \sum_{i=1}^n c_H(Z_i, z)\} D^\top W_H(z),$$

where  $c_H(Z_i, z)^{-1} = \sum_{t=1}^m K_H(Z_{it}, z)$  for  $i = 1, \dots, n$  and  $A = \text{diag}\{c_H(Z_2, z)^{-1}, \dots, c_H(Z_n, z)^{-1}\}$ .

We use the formula  $(A + BCD)^{-1} = A^{-1} - A^{-1}B(DA^{-1}B + C^{-1})^{-1}DA^{-1}$  to derive the inverse matrix, see Appendix B in Poirier (1995).

### 3 Nonparametric Estimator and Asymptotic Theory

A local linear regression approach is commonly used to estimate non-/semi-parametric models. The basic idea of this method is to apply Taylor expansion up to the second-order derivative. Throughout the paper we will use the notation that  $A_n \approx B_n$  to denote that  $B_n$  is the leading term of  $A_n$ , i.e.,  $A_n = B_n + (s.o.)$ , where  $(s.o.)$  denotes terms having probability order smaller than that of  $B_n$ . For each  $l = 1, \dots, p$ , we have the following Taylor expansion around  $z$ :

$$\theta_l(z_{it}) \approx \theta_l(z) + \{H\theta'_l(z)\}^\top [H^{-1}(z_{it} - z)] + \frac{1}{2} r_{H,l}(z_{it}, z), \quad (11)$$

where  $\theta'_l(z) = \partial\theta_l(z)/\partial z$  is the  $q \times 1$  vector of first order derive function,  $r_{H,l}(z_{it}, z) = \{H^{-1}(z_{it} - z)\}^\top \{H \frac{\partial^2 \theta_l(z)}{\partial z \partial z^\top} H\} \{H^{-1}(z_{it} - z)\}$ . Of course,  $\theta_l(z)$  approximates  $\theta_l(z_{it})$  and  $\theta'_l(z)$  approximates  $\theta'_l(z_{it})$  when  $z_{it}$  is close to  $z$ . Define  $\beta_l(z) = \{\theta_l(z), [H\theta'_l(z)]^\top\}^\top$ , a  $(q+1) \times 1$  column vector for  $l = 1, 2, \dots, p$ , and  $\beta(z) = \{\beta_1(z), \dots, \beta_p(z)\}^\top$ , a  $p \times (q+1)$  parameter matrix. The first column of  $\beta(z)$  is  $\theta(z)$ . Therefore, we will replace  $\theta(Z_{it})$  in (1) by  $\beta(z)G_{it}(z, H)$  for each  $i$  and  $t$ , where  $G_{it}(z, H) = [1, \{H^{-1}(Z_{it} - z)\}^\top]^\top$  is a  $(q+1) \times 1$  vector.

To make matrix operations simpler, we stack the matrix  $\beta(z)$  into a  $p(q+1) \times 1$  column vector and denote it by  $\text{vec}\{\beta(z)\}$ . Since  $\text{vec}(ABC) = (C^\top \otimes A)\text{vec}(B)$  and  $(A \otimes B)^\top = A^\top \otimes B^\top$ , where  $\otimes$  refers to Kronecker product, we have  $X_{it}^\top \beta(z)G_{it}(z, H) = \{G_{it}(z, H) \otimes X_{it}\}^\top \text{vec}\{\beta(z)\}$  for all  $i$  and  $t$ . Thus, we consider the following minimization problem

$$\min_{\beta(z)} [Y - R(z, H)\text{vec}\{\beta(z)\}]^\top S_H(z) [Y - R(z, H)\text{vec}\{\beta(z)\}] \quad (12)$$

where

$$R_i(z, H) = \begin{bmatrix} (G_{i,1}(z, H) \otimes X_{i1})^\top \\ \vdots \\ (G_{i,m}(z, H) \otimes X_{im})^\top \end{bmatrix} \text{ is an } m \times [p(q+1)] \text{ matrix,}$$

$$R(z, H) = [R_1(z, H)^\top, \dots, R_n(z, H)^\top]^\top \text{ is an } (nm) \times [p(q+1)] \text{ matrix.}$$

Simple calculations give

$$\begin{aligned} \text{vec}\{\widehat{\beta}(z)\} &= \{R(z, H)^\top S_H(z) R(z, H)\}^{-1} R(z, H)^\top S_H(z) Y \\ &= \text{vec}\{\beta(z)\} + \{R(z, H)^\top S_H(z) R(z, H)\}^{-1} (A_n/2 + B_n + C_n), \end{aligned} \quad (13)$$

where  $A_n = R(z, H)^\top S_H(z) \Pi(z, H)$ ,  $B_n = R(z, H)^\top S_H(z) D_0 \mu_0$ , and  $C_n = R(z, H)^\top S_H(z) V$ . The  $\{t + (i-1)m\}^{\text{th}}$  element of the column vector  $\Pi(z, H)$  is  $X_{it}^\top r_H(\widetilde{Z}_{it}, z)$ , where  $r_H(\cdot, \cdot) = \{r_{H,1}(\cdot, \cdot), \dots, r_{H,p}(\cdot, \cdot)\}^\top$  and  $r_{H,l}(\widetilde{Z}_{it}, z) = \{H^{-1}(Z_{it} - z)\}^\top \{H \frac{\partial^2 \theta_l(\widetilde{Z}_{it})}{\partial z \partial z^\top} H\} \{H^{-1}(Z_{it} - z)\}$  with  $\widetilde{Z}_{it}$  lying between  $Z_{it}$  and  $z$  for each  $i$  and  $t$ .

To derive the asymptotic distribution of  $\text{vec}\{\widehat{\beta}(z)\}$ , we first give some regularity conditions. Throughout this paper, we use  $M > 0$  to denote a finite constant, which may take a different value at different places.

**Assumption 1:** The random variables  $(X_{it}, Z_{it})$  are independently and identically distributed (i.i.d.) across the  $i$  index, and

- (a)  $E\|X_{it}\|^{2(1+\delta)} \leq M < \infty$  and  $E\|Z_{it}\|^{2(1+\delta)} \leq M < \infty$  hold for some  $\delta > 0$  and for all  $i$  and  $t$ .
- (b) The  $Z_{it}$  are continuous random variables with a p.d.f.  $f_t(z)$ . Also, for each  $z \in R^q$ ,  $f(z) = \sum_{t=1}^m f_t(z) > 0$ .

- (c) Denote  $\lambda_{it} = K_H(Z_{it}, z)$  and  $\varpi_{it} = \lambda_{it} / \sum_{t=1}^m \lambda_{it} \in (0, 1)$  for all  $i$  and  $t$ .  $\Psi(z) = |H|^{-1} \sum_{t=1}^m E[(1 - \varpi_{it}) \lambda_{it} X_{it} X_{it}^\top]$  is a nonsingular matrix.

- (d) Let  $f_t(z|X_{it})$  be the conditional pdf of  $Z_{it}$  at  $Z_{it} = z$  conditional on  $X_{it}$  and  $f_{t,s}(z_1, z_2|X_{it}, X_{js})$  be the joint conditional pdf of  $(Z_{it}, Z_{js})$  at  $(Z_{it}, Z_{js}) = (z_1, z_2)$  conditional on  $(X_{it}, X_{js})$  for  $t \neq s$  and any  $i$  and  $j$ .  $\theta(z)$ ,  $f_t(z)$ ,  $f_t(\cdot|X_{it})$ ,  $f_{t,s}(\cdot, \cdot|X_{it}, X_{js})$  are uniformly bounded in the domain of  $Z$  and are all twice continuously differentiable at  $z \in R^q$  for all  $t \neq s$  and  $i$  and  $j$ .

**Assumption 2:** Both  $X$  and  $Z$  have full column rank;  $\{X_{it,1}, \dots, X_{it,p}, \{X_{it,l}Z_{it,j} : l = 1, \dots, p, j = 1, \dots, q\}\}$  are linearly independent. If  $X_{it,l} \equiv X_{i,l}$  for at most one  $l \in \{1, \dots, p\}$ , i.e.,  $X_{i,l}$  does not depend on  $t$ , we assume  $E(X_{i,l}) \neq 0$ . The unobserved fixed effects  $\mu_i$  are i.i.d. with zero mean and a finite variance  $\sigma_\mu^2 > 0$ . The random errors  $v_{it}$  are assumed to be i.i.d. with a zero mean, finite variance  $\sigma_v^2$  and independent of  $Z_{it}$  and  $X_{it}$  for all  $i$  and  $t$ .  $Y_{it}$  is generated by equation (1).

**Assumption 3:**  $K(v) = \prod_{s=1}^q k(v_s)$  is a product kernel, and the univariate kernel function  $k(\cdot)$  is a uniformly bounded, symmetric (around zero) probability density function with a compact support  $[-1, 1]$ . In addition, define  $|H| = h_1 \cdots h_q$  and  $\|H\| = \sqrt{\sum_{j=1}^q h_j^2}$ . As  $n \rightarrow \infty$ ,  $\|H\| \rightarrow 0$ ,  $n|H| \rightarrow \infty$ .

The assumptions listed above are regular assumptions seen in nonparametric estimation literature. Assumption 1 apparently excludes the case of either  $X_{it}$  or  $Z_{it}$  being I(1); other than the moment restrictions, we do not impose I(0) structure on  $X_{it}$  across time, since this paper considers the case that  $m$  is a small finite number. Also, instead of imposing the smoothness assumption on  $f_t(\cdot|X_{it})$  and  $f_{t,s}(\cdot, \cdot|X_{it}, X_{is})$  as in Assumption 1(d), we can assume that  $f_t(z) E(X_{it}X_{it}^T|z)$  and  $f_{t,s}(z_1, z_2) E(X_{it}X_{js}^T|z_1, z_2)$  are uniformly bounded in the domain of  $Z$  and are all twice continuously differentiable at  $z \in R^q$  for all  $t \neq s$  and  $i$  and  $j$ . Our version of the smoothness assumption simplifies our notation in the proofs.

Assumption 2 indicates that  $X_{it}$  can contain a constant term of ones. The kernel function having a compact support in Assumption 3 is imposed for the sake of brevity of proof and can be removed at the cost of lengthy proofs. Specifically, the Gaussian kernel is allowed.

We use  $\hat{\theta}(z)$  to denote the first column of  $\hat{\beta}(z)$ . Then  $\hat{\theta}(z)$  estimates  $\theta(z)$ .

**THEOREM 3.1** *Under Assumptions 1-3, we have the following bias and variance for  $\hat{\theta}(z)$ , given a finite integer  $m > 0$ :*

$$\begin{aligned} \text{bias}(\hat{\theta}(z)) &= \Psi(z)^{-1} \Lambda(z) / 2 + O\left(n^{-1/2} |H| \ln(\ln n)\right) + o(\|H\|^2), \\ \text{var}(\hat{\theta}(z)) &= n^{-1} |H|^{-1} \sigma_v^2 \Psi(z)^{-1} \Gamma(z) \Psi(z)^{-1} + o(n^{-1} |H|^{-1}), \end{aligned}$$

where  $\Psi(z) = |H|^{-1} \sum_{t=1}^m E[(1 - \varpi_{it}) \lambda_{it} X_{it} X_{it}^T]$ ,  $\Lambda(z) = |H|^{-1} \sum_{t=1}^m E[(1 - \varpi_{it}) \lambda_{it} X_{it} X_{it}^T r_H(\tilde{Z}_{it}, z)] = O(\|H\|^2)$ ,  $\Gamma(z) = |H|^{-1} \sum_{t=1}^m E[(1 - \varpi_{it})^2 \lambda_{it}^2 X_{it} X_{it}^T]$ .

The first term of bias( $\hat{\theta}(z)$ ) results from the local approximation of  $\theta(z)$  by a linear function of

$z$ , which is of order  $O(\|H\|^2)$  as usual. The second term of  $\text{bias}(\widehat{\theta}(z))$  results from the unknown fixed effects  $\mu_i$ : (a) if we assumed  $\sum_{i=1}^n \mu_i = 0$ , this term is zero exactly; (b) the result indicates that the bias term is dominated by the first term and will vanish as  $n \rightarrow \infty$ .

In Appendix, we show that

$$\begin{aligned} |H|^{-1} \sum_{t=1}^m E(\lambda_{it} X_{it} X_{it}^T) &= \Phi(z) + o(\|H\|^2), \\ |H|^{-1} \sum_{t=1}^m E\left[\lambda_{it} X_{it} X_{it}^T r_H(\check{Z}_{it}, z)\right] &= \Phi(z) \left( \int K(u) u u^T du \right) \Theta_H(z) + o(\|H\|^2), \\ |H|^{-1} \sum_{t=1}^m E(\lambda_{it}^2 X_{it} X_{it}^T) &= \left( \int K^2(u) du \right) \Phi(z) + o(\|H\|^2), \end{aligned}$$

where  $\Phi(z) = \sum_{t=1}^m f_t(z) E(X_{1t} X_{1t}^T | z)$ , and  $\Theta_H(z) = \left[ \text{tr}\left(H \frac{\partial^2 \theta_1(z)}{\partial z \partial z^T} H\right), \dots, \text{tr}\left(H \frac{\partial^2 \theta_p(z)}{\partial z \partial z^T} H\right) \right]^T$ . Since  $0 < \varpi_{it} < 1$  for all  $i$  and  $t$ , the results above imply the existence of  $\Psi(z)$ ,  $\Lambda(z)$ , and  $\Gamma(z)$ . However, given a finite integer  $m > 0$ , we can not obtain explicitly the asymptotic bias and variance due to the random denominator appearing in  $\varpi_{it}$ .

Further, the following Theorem gives the asymptotic normality results for  $\widehat{\theta}(z)$ .

**THEOREM 3.2** *Under Assumptions 1-3, and assuming in addition that  $E|v_{it}|^{2+\delta} < \infty$  for some  $\delta > 0$ , and that  $\sqrt{n|H|}\|H\|^2 = O(1)$  as  $\rightarrow \infty$ , we have*

$$\sqrt{n|H|}\{\widehat{\theta}(z) - \theta(z) - \Psi(z)^{-1} \Lambda(z)/2\} \xrightarrow{d} N(0, \Sigma_{\theta(z)}),$$

where  $\Sigma_{\theta(z)} = \sigma_v^2 \Psi(z)^{-1} \Gamma(z) \Psi(z)^{-1}$ . Moreover, a consistent estimator for  $\Sigma_{\theta(z)}$  is given as follows:

$$\begin{aligned} \widehat{\Sigma}_{\theta(z)} &= S_p \widehat{\Omega}(z, H)^{-1} \widehat{J}(z, H) \widehat{\Omega}(z, H)^{-1} S_p^\top \xrightarrow{p} \Sigma_{\theta(z)}, \\ \widehat{\Omega}(z, H) &= n^{-1} |H|^{-1} R(z, H)^\top S_H(z) R(z, H) \\ \widehat{J}(z, H) &= n^{-1} |H|^{-1} R(z, H)^\top S_H(z) \widehat{V} \widehat{V}^\top S_H(z) R(z, H) \end{aligned}$$

where  $\widehat{V}$  is the vector of estimated residuals and  $S_p$  includes the first  $p$  rows of the  $p(q+1)$  identify matrix. Finally, consistent estimator for the leading bias can be easily obtained based on a nonparametric local quadratic regression result.

## 4 Testing Random Effects vs Fixed Effects

In this section we discuss how to test for the presence of random effects versus fixed effects in a semiparametric varying coefficient panel data model. The model remains as (1). The random effects specification assumes that  $\mu_i$  is uncorrelated with the regressors  $X_{it}$  and  $Z_{it}$ , while for the fixed effects case,  $\mu_i$  is allowed to be correlated with  $X_{it}$  and/or  $Z_{it}$  in an unknown way.

We are interested in testing the null hypothesis ( $H_0$ ) that  $\mu_i$  is a random effect versus the alternative hypothesis ( $H_1$ ) that  $\mu_i$  is a fixed effect. The null and alternative hypotheses can be written as

$$H_0 : \Pr\{E(\mu_i|Z_{i1}, \dots, Z_{im}, X_{i1}, \dots, X_{im}) \equiv 0\} = 1 \text{ for all } i, \quad (14)$$

$$H_1 : \Pr\{E(\mu_i|Z_{i1}, \dots, Z_{im}, X_{i1}, \dots, X_{im}) \neq 0\} > 0 \text{ for some } i, \quad (15)$$

while we keep the same setup given in model (1) under both  $H_0$  and  $H_1$ .

Our test statistic is based on the squared difference between the FE and RE estimators, which is asymptotically zero under  $H_0$  and positive under  $H_1$ . To simplify the proofs and save computing time, we use local constant estimator instead of local linear estimator for constructing our test. Then following the argument in Section 2 and Appendix 7.2, we have

$$\begin{aligned} \hat{\theta}_{FE}(z) &= \{X^\top S_H(z)X\}^{-1}X^\top S_H(z)Y \\ \hat{\theta}_{RE}(z) &= \{X^\top W_H(z)X\}^{-1}X^\top W_H(z)Y \end{aligned}$$

where  $X$  is a  $(nm) \times p$  matrix with  $X = (X_1^\top, \dots, X_n^\top)$ , and for each  $i$ ,  $X_i = (X_{i1}, \dots, X_{im})^\top$  is an  $m \times p$  matrix with  $X_{it} = [X_{it,1}, \dots, X_{it,p}]^\top$ . Motivated by Li, et al. (2002), we remove the random denominator of  $\hat{\theta}_{FE}(z)$  by multiplying  $X^\top S_H(z)X$  and our test statistic will be based on

$$\begin{aligned} T_n &= \int \{\hat{\theta}_{FE}(z) - \hat{\theta}_{RE}(z)\}^\top \{X^\top S_H(z)X\}^\top \{X^\top S_H(z)X\} \{\hat{\theta}_{FE}(z) - \hat{\theta}_{RE}(z)\} dz \\ &= \int \tilde{U}(z)^\top S_H(z)X X^\top S_H(z) \tilde{U}(z) dz \end{aligned}$$

since  $\{X^\top S_H(z)X\} \{\hat{\theta}_{FE}(z) - \hat{\theta}_{RE}(z)\} = X^\top S_H(z) \{Y - X\hat{\theta}_{RE}(z)\} \equiv X^\top S_H(z) \tilde{U}(z)$ . To simplify the statistic, we make several changes in  $T_n$ . Firstly, we simplify the integration calculation by replacing  $\tilde{U}(z)$  by  $\hat{U}$ , where  $\hat{U} \equiv \hat{U}(Z) = Y - B\{X, \hat{\theta}_{RE}(Z)\}$  and  $B\{X, \hat{\theta}_{RE}(Z)\}$  stacks up  $X_{it}^\top \hat{\theta}_{RE}(Z_{it})$  in the increasing order of  $i$  first then of  $t$ . Secondly, to overcome the complexity caused by the random

denominator in  $M_H(z)$ , we replace  $M_H(z)$  by  $M_D = I_{n \times m} - m^{-1}I_n \otimes (e_m e_m^\top)$  such that the fixed effects can be removed due to the fact that  $M_D D_0 = 0$ . With the above modification and also removing the  $i = j$  terms in  $T_n$  (since  $T_n$  contains two summations  $\sum_i \sum_j$ ), our further modified test statistic is given by

$$\tilde{T}_n \stackrel{def}{=} \sum_{i=1}^n \sum_{j \neq i} \hat{U}_i^\top Q_m \int K_H(Z_i, z) X_i^\top X_j K_H(Z_j, z) dz Q_m \hat{U}_j,$$

where  $Q_m = I_m - m^{-1}e_m e_m^\top$ . If  $|H| \rightarrow 0$  as  $n \rightarrow \infty$ , we obtain

$$\begin{aligned} & |H|^{-1} \int K_H(Z_i, z) X_i^\top X_j K_H(Z_j, z) dz \\ &= \begin{bmatrix} \bar{K}_H(Z_{i,1}, Z_{j,1}) X_{i,1}^\top X_{j,1} & \cdots & \bar{K}_H(Z_{i,1}, Z_{j,m}) X_{i,1}^\top X_{j,m} \\ \vdots & \ddots & \vdots \\ \bar{K}_H(Z_{i,m}, Z_{j,1}) X_{i,m}^\top X_{j,1} & \cdots & \bar{K}_H(Z_{i,m}, Z_{j,m}) X_{i,m}^\top X_{j,m} \end{bmatrix}, \end{aligned} \quad (16)$$

where  $\bar{K}_H(Z_{it}, Z_{js}) = \int K\{H^{-1}(Z_{it} - Z_{js}) + \omega\} K(\omega) d\omega$ . We then replace  $\bar{K}_H(Z_{it}, Z_{js})$  by  $K_H(Z_{it}, Z_{js})$ ; this replacement will not affect the essence of the test statistic since the local weight is untouched.

Now, our proposed test statistic is given by

$$\hat{T}_n = \frac{1}{n^2 |H|} \sum_{i=1}^n \sum_{j \neq i} \hat{U}_i^\top Q_m A_{i,j} Q_m \hat{U}_j \quad (17)$$

where  $A_{i,j}$  equals to the right-hand side of equation (16) after replacing  $\bar{K}_H(Z_{it}, Z_{js})$  by  $K_H(Z_{it}, Z_{js})$ . Finally, to remove the asymptotic bias term of the proposed test statistic, we calculate the leave-one-unit-out random-effects estimator of  $\theta(Z_{it})$ ; that is, for a given pair of  $(i, j)$  in the double summation of (17) with  $i \neq j$ ,  $\hat{\theta}_{RE}(Z_{it})$  is calculated without using the observations on the  $j^{th}$ -unit,  $\{(X_{jt}, Z_{jt}, Y_{jt})\}_{t=1}^m$  and  $\hat{\theta}_{RE}(Z_{jt})$  is calculated without using the observations on the  $i^{th}$ -unit.

We present the asymptotic properties of this test below and delay the proofs to Appendix 7.3.

**THEOREM 4.1** *Under Assumptions 1-3, and  $f_t(z)$  has a compact support  $\mathcal{S}$  for all  $t$ , and  $n\sqrt{|H|} \|H\|^4 \rightarrow 0$  as  $n \rightarrow \infty$ , then we have under  $H_0$  that*

$$J_n = n\sqrt{|H|} \hat{T}_n / \hat{\sigma}_0 \xrightarrow{d} N(0, 1) \quad (18)$$

where  $\hat{\sigma}_0^2 = \frac{1}{n^2 |H|} \sum_{i=1}^n \sum_{j \neq i} (\hat{V}_i^\top Q_m A_{i,j} Q_m \hat{V}_j)^2$  is a consistent estimator of

$$\sigma_0^2 = 2(1 - 1/m)^2 \sigma_v^4 \int K^2(u) du \sum_{t=1}^m \sum_{s=1}^t E \left\{ f_s(Z_{2t}) E \left[ (X_{1s}^\top X_{2t})^2 | Z_{2t} \right] \right\},$$

where  $\widehat{V}_{it} = Y_{it} - X_{it}^\top \widehat{\theta}_{FE}(Z_{it}) - \widehat{\mu}_i$  and for each pair of  $(i, j)$ ,  $i \neq j$ ,  $\widehat{\theta}_{FE}(Z_{it})$  is a leave-two-unit-out FE estimator without using the observations from the  $i^{\text{th}}$  and  $j^{\text{th}}$  units and  $\widehat{\mu}_i = \bar{Y}_i - m^{-1} \sum_{t=1}^m X_{it}^\top \widehat{\theta}_{FE}(Z_{it})$ . Under  $H_1$ ,  $\Pr[J_n > B_n] \rightarrow 1$  as  $n \rightarrow \infty$ , where  $B_n$  is any nonstochastic sequence with  $B_n = o(n\sqrt{|H|})$ .

Assuming that  $f_t(z)$  has a compact support  $\mathcal{S}_t$  for all  $t$  is to simplify the proof of  $\sup_{z \in \mathcal{S}} \|\widehat{\theta}_{RE}(z) - \theta(z)\| = o_p(1)$  as  $n \rightarrow \infty$ ; otherwise, some trimming procedure has to be placed to show the uniform convergence result and the consistency of  $\widehat{\sigma}_0^2$  as an estimator of  $\sigma_0^2$ . Theorem 4.1 states that the test statistic  $J_n = n\sqrt{|H|} \widehat{T}_n / \widehat{\sigma}_0$  is a consistent test for testing  $H_0$  against  $H_1$ . It is a one-sided test. If  $J_n$  is greater than the critical values from the standard normal distribution, we reject the null hypothesis at the corresponding significance levels.

## 5 Monte Carlo Simulations

In this section we report some Monte Carlo simulation results to examine the finite sample performance of the proposed estimator. The following data generating process is used:

$$Y_{it} = \theta_1(Z_{it}) + \theta_2(Z_{it})X_{it} + \mu_i + v_{it}, \quad (19)$$

where  $\theta_1(z) = 1 + z + z^2$ ,  $\theta_2(z) = \sin(z\pi)$ ,  $Z_{it} = w_{it} + w_{i,t-1}$ ,  $w_{it}$  is i.i.d. uniformly distributed in  $[0, \pi/2]$ ,  $X_{it} = 0.5X_{i,t-1} + \xi_{it}$ ,  $\xi_{it}$  is i.i.d.  $N(0, 1)$ . In addition,  $\mu_i = c_0 \bar{Z}_i + u_i$  for  $i = 2, \dots, n$  with  $c_0 = 0, 0.5$ , and  $1.0$ ,  $u_i$  is i.i.d.  $N(0, 1)$ . When  $c_0 \neq 0$ ,  $\mu_i$  and  $Z_{it}$  are correlated; we use  $c_0$  to control the correlation between  $\mu_i$  and  $\bar{Z}_i = m^{-1} \sum_{t=1}^m Z_{it}$ . Moreover,  $v_{it}$  is i.i.d.  $N(0, 1)$ ,  $w_{it}$ ,  $\xi_{it}$ ,  $u_i$  and  $v_{it}$  are independent of each other.

We report estimation results for both the proposed fixed-effects (FE) estimator and the random-effects (RE) estimator, see Appendix 7.2 for the asymptotic results of the RE estimator. To learn how the two estimators perform when we have fixed-effects model and when we have random-effects model, we use the integrated squared error as a standard measure of estimation accuracy:

$$ISE(\widehat{\theta}_l) = \int \{\widehat{\theta}_l(z) - \theta_l(z)\}^2 f(z) dz, \quad (20)$$

which can be approximated by the average mean squared error  $AMSE(\widehat{\theta}_l) = (nm)^{-1} \sum_{i=1}^n \sum_{t=1}^m [\widehat{\theta}_l(Z_{it}) - \theta_l(Z_{it})]^2$  for  $l = 1, 2$ . In Table 1 we present the average value of  $AMSE(\widehat{\theta}_l)$  from 1000 Monte Carlo experiments. We choose  $m = 3$  and  $n = 50, 100$ , and  $200$ .

Since the bias and variance of the proposed FE estimator do not depend on the values of the fixed effects, our estimates are the same for different values of  $c_0$ ; however, it is not true under the random-effects model. Therefore, the results derived from the FE estimator are only reported once in Table 1 since it is invariant to different values of  $c_0$ .

It is well-known that the performance of non/semiparametric models depends on the choice of bandwidth. Therefore, we propose a leave-**one-unit**-out cross validation method to automatically select the optimal bandwidth for estimating both the FE and RE models. Specifically, when estimating  $\theta(\cdot)$  at a point  $Z_{it}$ , we remove  $\{(X_{it}, Y_{it}, Z_{it})\}_{t=1}^m$  from the data and only use the rest of  $(n-1)m$  observations to calculate  $\hat{\theta}_{(-i)}(Z_{it})$ . In computing the RE estimate, the leave-one-unit-out cross validation method is just a trivial extension of the conventional leave-one-out cross validation method. The conventional leave-one-out method fails to provide satisfying result due to the existence of unknown fixed effects. Therefore, when calculating the FE estimator, we use the following modified leave-one-unit-out cross validation method:

$$\hat{H}_{opt} = \arg \min_H [Y - B\{X, \hat{\theta}_{(-1)}(Z)\}]^\top M_D^\top M_D [Y - B\{X, \hat{\theta}_{(-1)}(Z)\}], \quad (21)$$

where  $M_D = I_{n \times m} - m^{-1}I_n \otimes (e_m e_m^\top)$  satisfies  $M_D D_0 = 0$ ; this is used to remove the unknown fixed effects. In addition,  $B\{X, \hat{\theta}_{(-1)}(Z)\}$  stacks up  $X_{it}^\top \hat{\theta}_{(-i)}(Z_{it})$  in the increasing order of  $i$  first then of  $t$ . Simple calculations give

$$\begin{aligned} & [Y - B\{X, \hat{\theta}_{(-1)}(Z)\}]^\top M_D^\top M_D [Y - B\{X, \hat{\theta}_{(-1)}(Z)\}] \\ &= [B\{X, \theta(Z)\} - B\{X, \hat{\theta}_{(-1)}(Z)\}]^\top M_D^\top M_D [B\{X, \theta(Z)\} - B\{X, \hat{\theta}_{(-1)}(Z)\}] \\ & \quad + 2[B\{X, \theta(Z)\} - B\{X, \hat{\theta}_{(-1)}(Z)\}]^\top M_D^\top M_D V + V^\top M_D M_D V, \end{aligned} \quad (22)$$

where the last term does not depend on the bandwidth. If  $v_{it}$  is independent of the  $\{X_{js}, Z_{js}\}$  for all  $i$  and  $t$ , or  $(X_{it}, Z_{it})$  is strictly exogenous variable, then the second term has zero expectation because the linear transformation matrix  $M_D$  removes a cross-time **not** cross-sectional average from each variable, e.g.  $\tilde{Y}_{it} = Y_{it} - m^{-1} \sum_{s=1}^m Y_{is}$  for all  $i$  and  $t$ . Therefore, the first term is the dominate term in large sample and (21) is used to find an optimal smoothing matrix minimizing a weighted mean squared error of  $\{\hat{\theta}(Z_{it})\}$ . Of course, we could use other weight matrix in (21) instead of  $M_D$  as long as the weight matrix can remove the fixed effects and does not trigger non-zero expectation of the second term in (22).

Table 1 shows that the RE estimator performs better than the FE estimator when the true model is a random effects model. However, the FE estimator performs much better than the RE estimator when the true model is a fixed-effects model. This is expected since the RE estimator is inconsistent when the true model is the fixed effects model. Therefore, our simulation results indicate that a test for random effects against fixed effects will be always in demand when we analyze panel data models. In Table 2 we report simulation results of the proposed nonparametric test of random effects against fixed effects.

For the selection of the bandwidth  $h$ , for univariate case, Theorem 4.1 indicates that  $h \rightarrow 0$ ,  $nh \rightarrow \infty$ , and  $nh^{9/2} \rightarrow 0$  as  $n \rightarrow \infty$ ; if we take  $h \sim n^{-\alpha}$ , Theorem 4.1 requires  $\alpha \in (\frac{2}{9}, 1)$ . To fulfill both conditions  $nh \rightarrow \infty$  and  $nh^{9/2} \rightarrow 0$  as  $n \rightarrow \infty$ , we use  $\alpha = 2/7$ . Therefore, in producing Table 2, we use  $h = c(nm)^{-2/7}\hat{\sigma}_z$  to calculate the RE estimator with  $c$  taking a value from .8 , 1.0, and 1.2. Although the bandwidth chosen this way may not be optimal, the results in Table 2 show that the proposed test statistic is not very sensitive to the choice of  $h$  when  $c$  changes and that a moderate size distortion and descent power are consistent with the findings in the nonparametric tests literature. We conjecture that some bootstrap procedures can be used to reduce the size distortion in finite samples. We will leave this as a future research topic.

## 6 Conclusion

In this paper we proposed a local least squares method to estimate a fixed effects varying coefficient panel data model; a data-driven method was introduced to automatically find the optimal bandwidth for the proposed FE estimator. In addition, we introduced a new test statistic to test for random effects against fixed effects. Monte Carlo simulations indicate that the proposed estimator and test statistic have good finite sample performance.

## 7 Appendix

### 7.1 Proof of Theorem 3.1

To make our mathematical formula short, we introduce some simplified notations first: for each  $i$ ,  $t$ , and  $s$ ,  $\lambda_{it} = K_H(Z_{it}, z)$ ,  $c_H(Z_i, z)^{-1} = \sum_{t=1}^m \lambda_{it}$ , and for any positive integers  $i, j, t, s$

$$\begin{aligned} [\cdot]_{it,js} &= G_{it}(z, H) G_{js}^T(z, H) = \begin{bmatrix} 1 & G_{js1} & \cdots & G_{jsq} \\ G_{it1} & G_{it1}G_{js1} & \cdots & G_{it1}G_{jsq} \\ \vdots & \vdots & \ddots & \vdots \\ G_{itq} & G_{itq}G_{js1} & \cdots & G_{itq}G_{jsq} \end{bmatrix} \\ &= \begin{bmatrix} 1 & (H^{-1}(Z_{js} - z))^T \\ H^{-1}(Z_{it} - z) & H^{-1}(Z_{it} - z)(H^{-1}(Z_{js} - z))^T \end{bmatrix} \end{aligned} \quad (23)$$

where the  $(l+1)^{th}$  element of  $G_{js}(z, H)$  is  $G_{jst} = (Z_{jst} - z_t)/h_t$ ,  $l = 1, \dots, q$ . Simple calculations show that

$$\begin{aligned} [\cdot]_{i_1t_1, i_2t_2} [\cdot]_{j_1s_1, j_2s_2} &= \left( 1 + \sum_{j=1}^q G_{j_1s_1j} G_{i_2t_2j} \right) [\cdot]_{i_1t_1, j_2s_2}, \\ R_i(z, H)^T K_H(Z_i, z) e_m e_m^T K_H(Z_j, z) R_j(z, H) &= \sum_{t=1}^m \sum_{s=1}^m \lambda_{it} \lambda_{js} [\cdot]_{it,js} \otimes (X_{it} X_{js}^T) \end{aligned}$$

In addition, we obtain for a finite positive integer  $j$

$$|H|^{-1} \sum_{t=1}^m E \left[ \lambda_{it}^j [\cdot]_{it,it} | X_{it} \right] = \sum_{t=1}^m E(S_{t,j,1} | X_{it}) + O_p(\|H\|^2), \quad (24)$$

$$|H|^{-1} \sum_{t=1}^m E \left[ \lambda_{it}^{2j} \sum_{j'=1}^q G_{itj'}^2 [\cdot]_{it,it} | X_{it} \right] = \sum_{t=1}^m E(S_{t,j,2} | X_{it}) + O_p(\|H\|^2), \quad (25)$$

where

$$S_{t,j,1} = \begin{bmatrix} f_t(z|X_{it}) \int K^j(u) du & \frac{\partial f_t(z|X_{it})}{\partial z^T} H R_{K,j} \\ R_{K,j} H \frac{\partial f_t(z|X_{it})}{\partial z} & f_t(z|X_{it}) R_{K,j} \end{bmatrix} \quad (26)$$

$$S_{t,j,2} = \begin{bmatrix} f_t(z|X_{it}) \int K^{2j}(u) u^T u du & \frac{\partial f_t(z|X_{it})}{\partial z^T} H \Gamma_{K,2j} \\ \Gamma_{K,2j} H \frac{\partial f_t(z|X_{it})}{\partial z} & f_t(z|X_{it}) \Gamma_{K,2j} \end{bmatrix} \quad (27)$$

where  $R_{K,j} = \int K^j(u) u u^T du$  and  $\Gamma_{K,2j} = \int K^{2j}(u) (u^T u) (u u^T) du$ .

Moreover, for any finite positive integer  $j_1$  and  $j_2$ , we have

$$\begin{aligned} &|H|^{-2} \sum_{t=1}^m \sum_{s \neq t}^m E \left[ \lambda_{it}^{j_1} \lambda_{is}^{j_2} [\cdot]_{it,is} | X_{it}, X_{is} \right] \\ &= \sum_{t=1}^m \sum_{s \neq t}^m E \left( T_{j_1, j_2, 1}^{(t,s)} | X_{it}, X_{is} \right) + O_p(\|H\|^2) \end{aligned} \quad (28)$$

$$\begin{aligned}
& |H|^{-2} \sum_{t=1}^m \sum_{s \neq t}^m E \left[ \lambda_{it}^{j_1} \lambda_{is}^{j_2} \left( \sum_{j'=1}^q G_{itj'} G_{isj'} \right) [\cdot]_{it, is} | X_{it}, X_{is} \right] \\
&= \sum_{t=1}^m \sum_{s \neq t}^m E \left( T_{j_1, j_2, 2}^{(t, s)} | X_{it}, X_{is} \right) + O_p \left( \|H\|^2 \right)
\end{aligned} \tag{29}$$

where we define  $b_{j_1, j_2, i_1, i_2} = \int K^{j_1}(u) u_1^{2i_1} du \int K^{j_2}(u) u_1^{2i_2} du$

$$T_{j_1, j_2, 1}^{(t, s)} = \begin{bmatrix} f_{t, s}(z, z | X_{it}, X_{is}) b_{j_1, j_2, 0, 0} & \nabla_s^T f_{t, s}(z, z | X_{it}, X_{is}) H b_{j_1, j_2, 0, 1} \\ H \nabla_t f_{t, s}(z, z | X_{it}, X_{is}) b_{j_1, j_2, 1, 0} & H \nabla_{t, s}^2 f_{t, s}(z, z | X_{it}, X_{is}) H b_{j_1, j_2, 1, 1} \end{bmatrix}$$

and

$$T_{j_1, j_2, 2}^{(t, s)} = \begin{bmatrix} \text{tr} \left( H \nabla_{t, s}^2 f_{t, s}(z, z | X_{it}, X_{is}) H \right) & \nabla_t^T f_{t, s}(z, z | X_{it}, X_{is}) H \\ H \nabla_s f_{t, s}(z, z | X_{it}, X_{is}) & f_{t, s}(z, z | X_{it}, X_{is}) I_{q \times q} \end{bmatrix} b_{j_1, j_2, 1, 1},$$

with  $\nabla_s f_{t, s}(z, z | X_{it}, X_{is}) = \partial f_{t, s}(z, z | X_{it}, X_{is}) / \partial z_s$  and  $\nabla_{t, s}^2 f_{t, s}(z, z | X_{it}, X_{is}) = \partial^2 f_{t, s}(z, z | X_{it}, X_{is}) / (\partial z_t \partial z_s^T)$ .

The conditional bias and variance of  $\text{vec}(\hat{\beta}(z))$  are given as follows:

$$\text{Bias} \left[ \text{vec}(\hat{\beta}(z)) | \{X_{it}, Z_{it}\} \right] = \left[ R(z, H)^T S_H(z) R(z, H) \right]^{-1} R(z, H)^T S_H(z) [\Pi(z, H) / 2 + D_0 \mu_0];$$

$$\begin{aligned}
\text{Var} \left[ \text{vec}(\hat{\beta}(z)) | \{X_{it}, Z_{it}\} \right] &= \sigma_v^2 \left[ R(z, H)^T S_H(z) R(z, H) \right]^{-1} \left[ R(z, H)^T S_H^2(z) R(z, H) \right] \\
&\quad \times \left[ R(z, H)^T S_H(z) R(z, H) \right]^{-1}.
\end{aligned}$$

**Lemma 7.1** *If Assumption A3 holds, we have*

$$\left[ \sum_{i=1}^n c_H(Z_i, z) \right]^{-1} = O_p(n^{-1} |H| \ln(\ln n)). \tag{30}$$

Proof: Simple calculations give  $E(\sum_{t=1}^m K_H(Z_{it}, z)) = |H| f(z) + O(|H| \|H\|^2)$  and  $K_H(Z_{it}, z) = |H| f_t(z) + O(|H| \|H\|^2)$ , where  $f(z) = \sum_{t=1}^m f_t(z)$ . Next, we obtain for any small  $\varepsilon > 0$

$$\begin{aligned}
& \Pr \left\{ \max_{1 \leq i \leq n} \sum_{t=1}^m \lambda_{it} > \varepsilon^{-1} f(z) |H| \ln(\ln n) \right\} = 1 - \Pr \left\{ \max_{1 \leq i \leq n} \sum_{t=1}^m \lambda_{it} \leq \varepsilon^{-1} f(z) |H| \ln(\ln n) \right\} \\
&= 1 - \left\{ 1 - \Pr \left\{ \sum_{t=1}^m \lambda_{it} > \varepsilon^{-1} f(z) |H| \ln(\ln n) \right\} \right\}^n \leq 1 - \left\{ 1 - \frac{\varepsilon E(\sum_{t=1}^m \lambda_{it})}{f(z) |H| \ln(\ln n)} \right\}^n \\
&\leq 1 - \left\{ 1 - \varepsilon \left( 1 + M \|H\|^2 \right) / \ln(\ln n) \right\}^n \rightarrow 0 \text{ as } n \rightarrow \infty
\end{aligned}$$

where the first inequality uses the the generalized Chebyshev inequality and the limit is derived using the l'Hôpital's rule. This will complete the proof of this lemma.

**Lemma 7.2** *Under Assumptions 1-3, we have*

$$\left[ n^{-1} |H|^{-1} R(z, H)^T S_H(z) R(z, H) \right]^{-1} \approx \left[ |H|^{-1} \sum_{t=1}^m E \left( \varpi_{it} \lambda_{it} [\cdot]_{it, it} \otimes (X_{it} X_{it}^T) \right) \right]^{-1}$$

where  $\varpi_{it} = \lambda_{it} / \sum_{t=1}^m \lambda_{it} \in (0, 1)$  for all  $i$  and  $t$ .

Proof: First, simple calculation gives

$$\begin{aligned} A_n &= R(z, H)^T S_H(z) R(z, H) = R(z, H)^T W_H(z) M_H(z) R(z, H) \\ &= \sum_{i=1}^n R_i(z, H)^T K_H(Z_i, z) R_i(z, H) \\ &\quad - \sum_{j=1}^n \sum_{i=1}^n q_{ij} R_i(z, H)^T K_H(Z_i, z) e_m e_m^T K_H(Z_j, z) R_j(z, H) \\ &= \sum_{i=1}^n \sum_{t=1}^m \lambda_{it} [\cdot]_{it, it} \otimes (X_{it} X_{it}^T) - \sum_{i=1}^n q_{ii} \sum_{t=1}^m \sum_{s=1}^m \lambda_{it} \lambda_{is} [\cdot]_{it, is} \otimes (X_{it} X_{is}^T) \\ &\quad - \sum_{j=1}^n \sum_{i \neq j} q_{ij} \sum_{t=1}^m \sum_{s=1}^m \lambda_{it} \lambda_{js} [\cdot]_{it, js} \otimes (X_{it} X_{js}^T) \\ &= A_{n1} - A_{n2} - A_{n3}, \end{aligned}$$

where  $M_H(z) = I_{n \times m} - [Q \otimes (e_m e_m^T)] W_H(z)$ , and the typical elements of  $Q$  are  $q_{ii} = c_H(Z_i, z) - c_H(Z_i, z)^2 / \sum_{i=1}^n c_H(Z_i, z)$  and  $q_{ij} = -c_H(Z_i, z) c_H(Z_j, z) / \sum_{i=1}^n c_H(Z_i, z)$  for  $i \neq j$ . Here,  $c_H(Z_i, z) = (\sum_{t=1}^m \lambda_{it})^{-1}$  for all  $i$ .

Applying (24), (25), (28), and (29) to  $A_{n1}$ , we have  $n^{-1} |H|^{-1} A_{n1} \approx \sum_{t=1}^m E [S_{t,1,1} \otimes (X_{it} X_{it}^T)] + O_p(\|H\|^2) + O_p(n^{-\frac{1}{2}} |H|^{-\frac{1}{2}})$  if  $\|H\| \rightarrow 0$  and  $n|H| \rightarrow \infty$  as  $n \rightarrow \infty$ .

Apparently,  $\sum_{t=1}^m \varpi_{it} = 1$  for all  $i$ . In addition, since the kernel function  $K(\cdot)$  is zero outside the unit circle by Assumption 3, the summations in  $A_n$  are taken over units such that  $\|H^{-1}(Z_{it} - z)\| \leq$

1. By Lemma 7.1 and by the LLN given Assumption 1 (a), we obtain

$$\left\| \frac{1}{n|H| \sum_{i=1}^n c_H(Z_i, z)} \sum_{i=1}^n \sum_{t=1}^m \sum_{s=1}^m \varpi_{it} \varpi_{is} [\cdot]_{it, is} \otimes (X_{it} X_{is}^T) \right\| = O_p(n^{-1} \ln(\ln n))$$

and  $\left\| \frac{1}{n|H|} \sum_{i=1}^n \sum_{t=1}^m \sum_{s \neq t}^m \frac{\lambda_{it} \lambda_{is}}{\sum_{t=1}^m \lambda_{it}} [\cdot]_{it, is} \otimes (X_{it} X_{is}^T) \right\| \leq \frac{1}{2n|H|} \sum_{i=1}^n \sum_{t=1}^m \sum_{s \neq t}^m \sqrt{\lambda_{it} \lambda_{is}} \left\| [\cdot]_{it, is} \otimes (X_{it} X_{is}^T) \right\| = O_p(|H|)$ , where we use  $\sum_{t=1}^m \lambda_{it} \geq \lambda_{it} + \lambda_{is} \geq 2\sqrt{\lambda_{it} \lambda_{is}}$  for any  $t \neq s$ .

Hence, we have  $n^{-1} |H|^{-1} A_{n2} = n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m \varpi_{it} \lambda_{it} [\cdot]_{it, it} \otimes (X_{it} X_{it}^T) + O_p(|H|)$ . Denote  $d_{it} = \varpi_{it} \lambda_{it} [\cdot]_{it, it} \otimes (X_{it} X_{it}^T)$  and  $\Delta_n = n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m (d_{it} - E d_{it})$ . It is easy to

show that  $n^{-1} |H|^{-1} \Delta_n = O_p \left( n^{-1/2} |H|^{-1/2} \right)$ . Since  $E(\|d_{it}\|) \leq E \left[ \lambda_{it} \left\| [\cdot]_{it,it} \otimes (X_{it} X_{it}^T) \right\| \right] \leq M |H|$  holds for all  $i$  and  $t$ . Therefore,  $n^{-1} |H|^{-1} A_{n2} = |H|^{-1} \sum_{t=1}^m E \left[ \varpi_{it} \lambda_{it} [\cdot]_{it,it} \otimes (X_{it} X_{it}^T) \right] + o_p(1)$  exists, but we can not calculate the exact expectation due to the random denominator.

Consider  $A_{n3}$ . We have  $n^{-1} |H|^{-1} \|A_{n3}\| = O_p \left( |H|^2 \ln(\ln n) \right)$  by Lemma 7.1, Assumption 1, and the fact that  $n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m I(\|H^{-1}(Z_{it} - z)\| \leq 1) = 2f(z) + O_p \left( \|H\|^2 \right) + O_p \left( n^{-1/2} |H|^{-1/2} \right)$ .

Hence, we obtain

$$\begin{aligned} n^{-1} |H|^{-1} A_n &\approx n^{-1} |H|^{-1} A_{n1} - n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m \varpi_{it} \lambda_{it} [\cdot]_{it,it} \otimes (X_{it} X_{it}^T) \\ &= n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m (1 - \varpi_{it}) \lambda_{it} [\cdot]_{it,it} \otimes (X_{it} X_{it}^T) \\ &= |H|^{-1} \sum_{t=1}^m E \left[ (1 - \varpi_{it}) \lambda_{it} [\cdot]_{it,it} \otimes (X_{it} X_{it}^T) \right] + o_p(1). \end{aligned}$$

This will complete the proof of this Lemma.

**Lemma 7.3** *Under Assumptions 1-3, we have*

$$n^{-1} |H|^{-1} R(z, H)^T S_H(z) \Pi(z, H) \approx |H|^{-1} \sum_{t=1}^m E \left[ (1 - \varpi_{it}) \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H \left( \tilde{Z}_{it}, z \right) \right].$$

Proof: Simple calculations give

$$\begin{aligned} B_n &= R(z, H)^T S_H(z) \Pi(z, H) \\ &= \sum_{i=1}^n \sum_{t=1}^m \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H \left( \tilde{Z}_{it}, z \right) - \sum_{j=1}^n \sum_{i=1}^n q_{ij} \sum_{s=1}^m \sum_{t=1}^m \lambda_{js} \lambda_{it} (G_{it} \otimes X_{it}) X_{js}^T r_H \left( \tilde{Z}_{js}, z \right) \\ &= \sum_{i=1}^n \sum_{t=1}^m \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H \left( \tilde{Z}_{it}, z \right) - \sum_{i=1}^n q_{ii} \sum_{t=1}^m \lambda_{it}^2 (G_{it} \otimes X_{it}) X_{it}^T r_H \left( \tilde{Z}_{it}, z \right) \\ &\quad - \sum_{i=1}^n q_{ii} \sum_{t=1}^m \sum_{s \neq t}^m \lambda_{is} \lambda_{it} (G_{it} \otimes X_{it}) X_{is}^T r_H \left( \tilde{Z}_{is}, z \right) \\ &\quad - \sum_{j=1}^n \sum_{i \neq j}^n q_{ij} \sum_{t=1}^m \sum_{s=1}^m \lambda_{js} \lambda_{it} (G_{it} \otimes X_{it}) X_{js}^T r_H \left( \tilde{Z}_{js}, z \right) \\ &= B_{n1} - B_{n2} - B_{n3} - B_{n4}, \end{aligned}$$

where  $\Pi(z, H)$  is defined in Section 3. Using the same method in the proof of Lemma 7.2, we show  $n^{-1} |H|^{-1} B_n \approx n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m (1 - \varpi_{it}) \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H \left( \tilde{Z}_{it}, z \right)$ .

For  $l = 1, \dots, k$  we have

$$\begin{aligned} |H|^{-1} E [\lambda_{it} r_{H,l}(Z_{it}, z) | X_{it}] &= f_t(z | X_{it}) \left( \int K(u) u u^T du \right) \Theta_H(z) + O_p(\|H\|^4) \\ |H|^{-1} E [\lambda_{it} r_{H,l}(Z_{it}, z) H^{-1}(Z_{it} - z) | X_{it}] &= O_p(\|H\|^3), \end{aligned}$$

and  $E(n^{-1} |H|^{-1} B_{n1}) \approx \left\{ [\Phi(z) (\int K(u) u u^T du) \Theta_H(z)]^T, O(\|H\|^3) \right\}^T$ , where

$$\Theta_H(z) = \left[ \text{tr} \left( H \frac{\partial^2 \theta_1(z)}{\partial z \partial z^T} H \right), \dots, \text{tr} \left( H \frac{\partial^2 \theta_k(z)}{\partial z \partial z^T} H \right) \right]^T.$$

Similarly we can show that  $\text{Var}(n^{-1} |H|^{-1} B_{n1}) = O(n^{-1} |H|^{-1} \|H\|^4)$  if  $E(\|X_{it} X_{is}^T X_{it} X_{is}^T\|) < M < \infty$  for all  $t$  and  $s$ .

In addition, it is easy to show that  $n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m \varpi_{it} \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H(\tilde{Z}_{it}, z) = n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m E[\varpi_{it} \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H(\tilde{Z}_{it}, z)] + O_p(n^{-1/2} |H|^{-1/2} \|H\|^2)$ , where  $|H|^{-1} \sum_{t=1}^m E[\varpi_{it} \lambda_{it} (G_{it} \otimes X_{it}) X_{it}^T r_H(\tilde{Z}_{it}, z)] \leq |H|^{-1} \sum_{t=1}^m E[\lambda_{it} \|(G_{it} \otimes X_{it}) X_{it}^T r_H(\tilde{Z}_{it}, z)\|] \leq M \|H\|^2 < \infty$  for all  $i$  and  $t$ .

This will complete the proof of this lemma.

**Lemma 7.4** *Under Assumptions 1-3, we have*

$$n^{-1} |H|^{-1} R(z, H)^T S_H(z) D_0 \mu_0 = O_p(n^{-1/2} |H| \ln(\ln n)).$$

Proof: Simple calculations give  $M_H(z) D_0 \mu_0 = \bar{\mu} M_H(z) (e_n \otimes e_m)$ , where  $\bar{\mu} = n^{-1} \sum_{i=1}^n \mu_i$ . It follows that

$$\begin{aligned} C_n &= R(z, H)^T S_H(z) D_0 \mu_0 = \bar{\mu} R(z, H)^T S_H(z) (e_n \otimes e_m) \\ &= \bar{\mu} \sum_{i=1}^n \sum_{t=1}^m R_i^T K_i e_m - \bar{\mu} \sum_{j=1}^n \left( \sum_{t=1}^m \lambda_{jt} \right) \sum_{i=1}^n q_{ij} R_i^T K_i e_m \\ &= \bar{\mu} \sum_{i=1}^n \sum_{t=1}^m \lambda_{it} (G_{it} \otimes X_{it}) - \bar{\mu} \sum_{j=1}^n \left( \sum_{t=1}^m \lambda_{jt} \right) \sum_{i=1}^n q_{ij} \sum_{t=1}^m \lambda_{it} (G_{it} \otimes X_{it}) \\ &= n \bar{\mu} \left[ \sum_{i=1}^n \left( \sum_{t=1}^m \lambda_{it} \right)^{-1} \right]^{-1} \sum_{i=1}^n \sum_{t=1}^m \varpi_{it} (G_{it} \otimes X_{it}) \end{aligned}$$

and we obtain  $n^{-1} |H|^{-1} C_n = \bar{\mu} O_p(|H| \ln(\ln n))$  by (a) Lemma 7.1, (b) for all  $l = 1, \dots, q$ ,  $k((Z_{it,l} - z_l)/h) = 0$  if  $|Z_{it,l} - z_l| > h$  by Assumption 3, (c)  $\varpi_{it} \leq 1$ , and (d)  $E\|X_{it}\|^{1+\delta} < M < \infty$

for some  $\delta > 0$  by Assumption 1. Since  $\mu_i \sim iid(0, \sigma_\mu^2)$ , we have  $\bar{\mu} = O_p(n^{-1/2})$ . It follows that  $n^{-1} |H| C_n = O_p(n^{-1/2} |H| \ln(\ln n))$ .

**Lemma 7.5** *Under Assumptions 1-3, we have*

$$n^{-1} |H|^{-1} R(z, H)^T S_H^2(z) R(z, H) \approx |H|^{-1} \sum_{t=1}^m E \left[ (1 - \varpi_{it})^2 \lambda_{it}^2 [\cdot]_{it} \otimes (X_{it} X_{it}^T) \right].$$

Proof: Simple calculations give

$$\begin{aligned} D_n &= R(z, H)^T S_H^2(z) R(z, H) = R(z, H)^T W_H(z) M_H(z) M_H(z)^T W_H(z) R(z, H) \\ &= \sum_{i=1}^n R_i(z, H)^T K_H^2(Z_i, z) R_i(z, H) - 2 \sum_{j=1}^n \sum_{i=1}^n q_{ji} R_j(z, H)^T K_H^2(Z_j, z) e_m e_m^T K_H(Z_i, z) R_i(z, H) \\ &\quad + \sum_{j=1}^n \sum_{i=1}^n \sum_{i'=1}^n q_{ij} q_{ji'} R_i(z, H)^T K_H(Z_i, z) e_m e_m^T K_H^2(Z_j, z) e_m e_m^T K_H(Z_{i'}, z) R_{i'}(z, H) \\ &= D_{n1} - 2D_{n2} + D_{n3}. \end{aligned}$$

Using the same method in the proof of Lemma 7.2, we show  $D_n \approx \sum_{i=1}^n \sum_{t=1}^m (1 - \varpi_{it})^2 \lambda_{it}^2 [\cdot]_{it} \otimes (X_{it} X_{it}^T)$ . It is easy to show that  $n^{-1} |H|^{-1} D_{n1} = n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m \lambda_{it}^2 [\cdot]_{it} \otimes (X_{it} X_{it}^T) = \sum_{t=1}^m E [S_{t,2,1} \otimes (X_{it} X_{it}^T)] + O_p(\|H\|^2) + O_p(n^{-1/2} |H|^{-1/2})$ .

Also, we obtain  $n^{-1} |H|^{-1} \sum_{i=1}^n \sum_{t=1}^m (1 - \varpi_{it})^2 \lambda_{it}^2 [\cdot]_{it} \otimes (X_{it} X_{it}^T) = \varkappa(z) + O_p(n^{-1/2} |H|^{-1/2})$ , where  $\varkappa(z) = |H|^{-1} \sum_{t=1}^m E \left[ (1 - \varpi_{it})^2 \lambda_{it}^2 [\cdot]_{it} \otimes (X_{it} X_{it}^T) \right] \leq |H|^{-1} \sum_{t=1}^m E \left[ \lambda_{it}^2 \left\| [\cdot]_{it} \otimes (X_{it} X_{it}^T) \right\| \right] \leq M < \infty$  for all  $i$  and  $t$ .

The four lemmas above are enough to give the result of Theorem 3.1. Moreover, applying Liapouuov's CLT will give the result of Theorem 3.2. Since the proof is a rather standard procedure, we drop the details for compactness of the paper.

## 7.2 Technical Sketch—Random Effects Estimator

The RE estimator,  $\hat{\theta}_{RE}(\cdot)$ , is the solution to the following optimization problem:

$$\min_{\beta(z)} [Y - R(z, H) \text{vec}(\beta(z))]^T W_H(z) [Y - R(z, H) \text{vec}(\beta(z))];$$

that is, we have

$$\begin{aligned} &\text{vec}(\hat{\beta}_{RE}(z)) \\ &= \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} R(z, H)^T W_H(z) Y \\ &= \text{vec}(\beta(z)) + \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} (\tilde{A}_n/2 + \tilde{B}_n + \tilde{C}_n) \end{aligned}$$

where  $\tilde{A}_n = R(z, H)^T W_H(z) \Pi(z, H)$ ,  $\tilde{B}_n = R(z, H)^T W_H(z) D_0 \mu_0$ , and  $\tilde{C}_n = R(z, H)^T W_H(z) V$ . Its asymptotic results are as follows.

**Lemma 7.6** *Under Assumptions 1-3, and  $E(X_{it}X_{it}^T|z)$  and  $E(\mu_i X_{it}|z)$  have continuous second-order derivative at  $z \in R^q$ . Also,  $\sqrt{n|H|}\|H\|^2 = O(1)$  as  $n \rightarrow \infty$ , and  $E(|v_{it}|^{2+\delta}) < \infty$  and  $E(|\mu_i|^{2+\delta}) < M < \infty$  for all  $i$  and  $t$  and for some  $\delta > 0$ , we have under  $H_0$*

$$\sqrt{n|H|} \left( \hat{\theta}_{RE}(z) - \theta(z) - \left( \int K(u) uu^T du \right) \Theta_H(z) \right) \xrightarrow{d} N(0, \Sigma_{\theta(z), RE}), \quad (31)$$

where  $\Sigma_{\theta(z), RE} = (\sigma_\mu^2 + \sigma_v^2) \Phi(z)^{-1} \int K^2(u) du$  and  $\Phi(z) = \sum_{t=1}^m f_t(z) E(X_{1t}X_{1t}^T|z)$ . Under  $H_1$ , we have

$$Bias(\hat{\theta}_{RE}(z)) = \left( \int K(u) uu^T du \right) \tilde{\Theta}_H(z) + \Phi(z)^{-1} \sum_{t=1}^m f_t(z) E(\mu_1 X_{1t}|z) + o(\|H\|^2), \quad (32)$$

$$Var(\hat{\theta}_{RE}(z)) = n^{-1} |H|^{-1} \sigma_v^2 \Phi(z)^{-1} \int K^2(u) du, \quad (33)$$

where  $\Theta_H(z)$  is given in the proof of Lemma 7.3 and  $\tilde{\Theta}_H(z)$  is given in the proof of this lemma.

**Proof of Lemma 7.6:** First, we have the following decomposition

$$\sqrt{n|H|} [\hat{\theta}_{RE}(z) - \theta(z)] = \sqrt{n|H|} [\hat{\theta}_{RE}(z) - E(\hat{\theta}_{RE}(z))] + \sqrt{n|H|} [E(\hat{\theta}_{RE}(z)) - \theta(z)],$$

where we can show that the first term converges to a normal distribution with mean zero by Liapouov's CLT (the details are dropped since it is a rather standard proof), and the second term contributes to the asymptotic bias. Since it will cause no notational confusion, we drop the subscription 'RE'. Below, we use  $Bias_i \{\hat{\theta}(z)\}$  and  $Var_i \{\hat{\theta}(z)\}$  to denote the respective bias and variance of  $\hat{\theta}_{RE}(z)$  under  $H_0$  if  $i = 0$  and under  $H_1$  if  $i = 1$ .

First, under  $H_0$ , the bias and variance of  $\hat{\theta}(z)$  are as follows:  $Bias_0 \{\hat{\theta}(z) | \{(X_{it}, Z_{it})\}\} = S_p \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} R(z, H)^T W_H(z) \Pi(z, H) / 2$  and

$$\begin{aligned} & Var_0 \left\{ \hat{\theta}(z) | \{(X_{it}, Z_{it})\} \right\} \\ &= S_p \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} \left[ R(z, H)^T W_H(z) Var(UU^T) W_H(z) R(z, H) \right] \\ & \times \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} S_p^T. \end{aligned}$$

It is simple to show that  $Var(UU^T) = \sigma_\mu^2 I_n \otimes (e_m e_m^T) + \sigma_v^2 I_{n \times m}$ .

Next, under  $H_1$ , we notice that  $Bias_1 \left\{ \hat{\theta}(z) \mid \{(X_{it}, Z_{it})\} \right\}$  is the sum of  $Bias_0 \left\{ \hat{\theta}(z) \mid \{(X_{it}, Z_{it})\} \right\}$  plus an additional term  $S_p \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} R(z, H)^T W_H(z) D_0 \mu_0$ , and that

$$\begin{aligned} Var_1 \left\{ \hat{\theta}(z) \mid \{(X_{it}, Z_{it})\} \right\} &= \sigma_v^2 S_p \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} \left[ R(z, H)^T W_H(z)^2 R(z, H) \right] \\ &\quad \times \left[ R(z, H)^T W_H(z) R(z, H) \right]^{-1} S_p^T. \end{aligned}$$

Denote  $m(z) = \sum_{t=1}^m f_t(z) E(\mu_1 X_{1t} | z)$ . Under Assumptions 1-3, and  $E(|\mu_i|^{2+\delta}) < M < \infty$  and  $E(\|X_{it}\|^{2+\delta}) < M < \infty$  for all  $i$  and  $t$  and for some  $\delta > 0$ , we show that

$$\begin{aligned} n^{-1} |H|^{-1} S_p R(z, H)^T W_H(z) D_0 \mu_0 &= n^{-1} |H|^{-1} S_p \sum_{i=1}^n \mu_i \sum_{t=1}^m \lambda_{it} (G_{it} \otimes X_{it}) \\ &= \sum_{t=1}^m f_t(z) E(\mu_1 X_{1t} | z) + tr \left( \left( \int K(u) uu^T du \right) H \frac{\partial^2 m(z)}{\partial z \partial z^T} H \right) + O_p \left( \frac{1}{\sqrt{n|H|}} \right), \end{aligned} \quad (34)$$

which is a non-zero constant plus a term of  $o_p(1)$  under  $H_1$ . Basing on the facts that  $R(z, H)^T W_H(z) R(z, H)$  is  $A_{n1}$  in Lemma 7.2 and that  $R(z, H)^T W_H(z) \Pi(z, H)$  is  $B_{n1}$  in Lemma 7.3, we have

$$Bias_0 \left\{ \hat{\theta}(z) \right\} = \left( \int K(u) uu^T du \right) \Theta_H(z) + o(\|H\|^2). \quad (35)$$

Combining (34) and (35), we obtain (32) with  $\tilde{\Theta}_H(z) = \left[ tr \left( H \frac{\partial^2 \tilde{\theta}_1(z)}{\partial z \partial z^T} H \right), \dots, tr \left( H \frac{\partial^2 \tilde{\theta}_p(z)}{\partial z \partial z^T} H \right) \right]^T$  with  $\tilde{\theta}_l(z) = \theta_l(z) + m_l(z)$  for  $l = 1, \dots, p$ . Hence, under  $H_1$ , the bias of the RE estimator will not vanish as  $n \rightarrow \infty$ , and this leads to the inconsistency of the RE estimator under  $H_1$ .

As for the asymptotic variance, we can easily show that under  $H_0$

$$Var_0 \left\{ \hat{\theta}(z) \right\} = n^{-1} |H|^{-1} (\sigma_\mu^2 + \sigma_v^2) \Phi(z)^{-1} \int K^2(u) du, \quad (36)$$

and under  $H_1$

$$Var_1 \left\{ \hat{\theta}(z) \right\} = n^{-1} |H|^{-1} \sigma_v^2 \Phi(z)^{-1} \int K^2(u) du, \quad (37)$$

where we have recognized that  $R(z, H)^T W_H(z)^2 R(z, H)$  is  $D_{n1}$  in Lemma 7.5, and the leading term of  $R(z, H)^T W_H(z) Var(UU^T) W_H(z) R(z, H)$  is  $(\sigma_\mu^2 + \sigma_v^2) R(z, H)^T W_H(z)^2 R(z, H)$ .

### 7.3 Proof of Theorem 4.1

Define  $\Delta_i = (\Delta_{i1}, \dots, \Delta_{im})^T$  with  $\Delta_{it} = X_{it} \left( \theta(Z_{it}) - \hat{\theta}_{RE}(Z_{it}) \right)$ . Since  $M_D D_0 = 0$ , we can decompose the proposed statistic into three terms

$$\begin{aligned} \hat{T}_n &= \frac{1}{n^2 |H|} \sum_{i=1}^n \sum_{j \neq i} \hat{U}_i^T Q_m A_{i,j} Q_m \hat{U}_j \\ &= \frac{1}{n^2 |H|} \sum_{i=1}^n \sum_{j \neq i} \Delta_i^T Q_m A_{i,j} Q_m \Delta_j + \frac{2}{n^2 |H|} \sum_{i=1}^n \sum_{j \neq i} \Delta_i^T Q_m A_{i,j} Q_m V_j \\ &\quad + \frac{1}{n^2 |H|} \sum_{i=1}^n \sum_{j \neq i} V_i^T Q_m A_{i,j} Q_m V_j \\ &= T_{n1} + 2T_{n2} + T_{n3} \end{aligned}$$

where  $V_i = (v_{i1}, \dots, v_{im})^T$  is the  $m \times 1$  error vector. Since  $\hat{\theta}_{RE}(Z_{it})$  does not depend on the  $j$ th unit observations and  $\hat{\theta}_{RE}(Z_{jt})$  does not depend on the  $i$ th unit observations for a pair of  $(i, j)$ , it is easy to see that  $E(T_{n2}) = 0$ . The proofs fall into the standard procedures seen in the literature of nonparametric tests. We therefore give a very brief proof below.

Firstly, applying Hall's (1984) CLT, we can show that under both  $H_0$  and  $H_1$

$$n\sqrt{|H|}T_{n3} \xrightarrow{d} N(0, \sigma_0^2) \quad (38)$$

by defining  $H_n(\chi_i, \chi_j) = V_i^T Q_m A_{i,j} Q_m V_j$  with  $\chi_i = (X_i, Z_i, V_i)$ , which a symmetric, centred and degenerate variable. We are able to show that

$$\frac{E[G_n^2(\chi_1, \chi_2)] + n^{-1}E[H_n^4((\chi_1, \chi_2))]}{\{E[H_n^2((\chi_1, \chi_2))]\}^2} = \frac{O(|H|^3) + O(n^{-1}|H|)}{O(|H|^2)} \rightarrow 0$$

if  $|H| \rightarrow 0$  and  $n|H| \rightarrow \infty$  as  $n \rightarrow \infty$ , where  $G_n(\chi_1, \chi_2) = E_{\chi_i}[H_n((\chi_1, \chi_i))H_n((\chi_2, \chi_i))]$ . In addition,  $\text{var}(n\sqrt{|H|}T_{n3}) = 2|H|^{-1}E(H_n^2(\chi_1, \chi_2)) \approx 2(1 - m^{-1})^2 \sigma_v^4 \sum_{t=1}^m \sum_{s=1}^m |H|^{-1}E[K_H^2(Z_{1s}, Z_{2t})(X_{1s}^T X_{2t})^2] = \sigma_0^2 + o(1)$ .

Secondly, we can show that  $n\sqrt{|H|}T_{n2} = O_p(\|H\|^2) + O_p(n^{-1/2}|H|^{-1/2})$  under  $H_0$  and  $n\sqrt{|H|}T_{n2} = O_p(1)$  under  $H_1$ . Moreover, we have, under  $H_0$ ,  $n\sqrt{|H|}T_{n1} = O_p(n\sqrt{|H|}\|H\|^4)$ ; under  $H_1$ ,  $n\sqrt{|H|}T_{n1} = O_p(n\sqrt{|H|})$ .

Finally, to estimate  $\sigma_0^2$  consistently under both  $H_0$  and  $H_1$ , we replace the unknown  $V_i$  and  $V_j$  in  $T_{n3}$  by the estimated residual vectors from the FE estimator. Simple calculations show that

the typical element of  $\hat{V}_i Q_m$  is  $\tilde{v}_{it} = y_{it} - X_{it}^T \hat{\theta}_{FE}(Z_{it}) - v_{it} - \left( \bar{y}_i - m^{-1} \sum_{t=1}^m X_{it}^T \hat{\theta}_{FE}(Z_{it}) - \bar{v}_i \right)$   
 $= \tilde{\Delta}_{it} - (v_{it} - \bar{v}_i)$ , where  $\tilde{\Delta}_{it} = X_{it}^T \left( \theta(Z_{it}) - \hat{\theta}_{FE}(Z_{it}) \right) - m^{-1} \sum_{t=1}^m X_{it}^T \left( \theta(Z_{it}) - \hat{\theta}_{FE}(Z_{it}) \right) =$   
 $\sum_{l=1}^m q_{lt} X_{il}^T \left( \theta(Z_{il}) - \hat{\theta}_{FE}(Z_{il}) \right)$  with  $q_{tt} = 1 - 1/m$  and  $q_{lt} = -1/m$  for  $l \neq t$ . The leave-two-unit-  
out FE estimator does not use the observations from the  $i$ th and  $j$ th units for a pair  $(i, j)$ , and this  
leads to  $E \left( \hat{V}_i^T Q_m A_{i,j} Q_m \hat{V}_j \right)^2 \approx \sum_{t=1}^m \sum_{s=1}^m E \left[ K_H^2(Z_{it}, Z_{js}) (X_{it}^T X_{js})^2 \left( \tilde{\Delta}_{it}^2 \tilde{\Delta}_{js}^2 + \tilde{\Delta}_{it}^2 \tilde{v}_{js}^2 + \tilde{\Delta}_{js}^2 \tilde{v}_{it}^2 + \tilde{v}_{it}^2 \tilde{v}_{js}^2 \right) \right]$   
 $\approx \sum_{t=1}^m \sum_{s=1}^m E \left[ K_H^2(Z_{it}, Z_{js}) (X_{it}^T X_{js})^2 \tilde{v}_{it}^2 \tilde{v}_{js}^2 \right]$ , where  $\tilde{v}_{it} = v_{it} - \bar{v}_i$  and  $\bar{v}_i = m^{-1} \sum_{t=1}^m v_{it}$ .
